

**53 year old F comes to clinic complaining of “allergic reactions” almost every day for the last 5 months. She has broken out in hives. She has experienced hand swelling and lip swelling episodes lasting for 48 hours. She tried some Benadryl with only little relief. She saw her primary doctor a month ago, who initially recommended she stop her new blood pressure pill (Lisinopril, an ACE-inhibitor), but she is still having “allergic reactions.” Her PCP did blood testing for foods, and now she is scared to eat many things which were mildly positive.**

**Case #3**

**Answer it:**
